Quiz, 10 questions

~	Cong	ratulations! You passed!	Next Item
1/1 point	1.	Which notation would you use to denote the 3rd layer's activations example from the 8th minibatch? $a^{[8]\{7\}(3)}$ $a^{[3]\{7\}(8)}$ $a^{[3]\{8\}(7)}$ Correct $a^{[8]\{3\}(7)}$	when the input is the 7th
1/1 point	2.	Which of these statements about mini-batch gradient descent do you should implement mini-batch gradient descent without different mini-batches, so that the algorithm processes all number time (vectorization). Training one epoch (one pass through the training set) using descent is faster than training one epoch using batch gradient. One iteration of mini-batch gradient descent (computing one faster than one iteration of batch gradient descent.	an explicit for-loop over nini-batches at the same g mini-batch gradient ent descent.
1/1 point	3.	Why is the best mini-batch size usually not 1 and not m, but instead If the mini-batch size is m, you end up with batch gradient of process the whole training set before making progress. Correct If the mini-batch size is m, you end up with stochastic gradie usually slower than mini-batch gradient descent. Un-selected is correct If the mini-batch size is 1, you lose the benefits of vectorizate the mini-batch. Correct If the mini-batch size is 1, you end up having to process the before making any progress. Un-selected is correct	ent descent, which has to

1 / 1 point 4. Suppose your learning algorithm's cost J, plotted as a function of the number of iterations, looks like this:

Which of the following do you agree with?

If you're using mini-batch gradient descent, this looks acceptable. But if you're using batch gradient descent, something is wrong.

Correct

- If you're using mini-batch gradient descent, something is wrong. But if you're using batch gradient descent, this looks acceptable.
- Whether you're using batch gradient descent or mini-batch gradient descent, this looks acceptable.
- Whether you're using batch gradient descent or mini-batch gradient descent, something is wrong.

Suppose the temperature in Casablanca over the first three days of January are the same:

Jan 1st: $heta_1=10^oC$

Jan 2nd: $heta_2 10^o C$

(We used Fahrenheit in lecture, so will use Celsius here in honor of the metric world.)

Say you use an exponentially weighted average with eta=0.5 to track the temperature: $v_0=0$, $v_t = eta v_{t-1} + (1-eta) heta_t$. If v_2 is the value computed after day 2 without bias correction, and $v_2^{corrected}$ is the value you compute with bias correction. What are these values? (You might be able to do this without a calculator, but you don't actually need one. Remember what is bias correction doing.)

Correct

- $v_2 = 10$, $v_2^{corrected} = 7.5$
- $v_2=10$, $v_2^{corrected}=10$
- $v_2 = 7.5, v_2^{corrected} = 7.5$

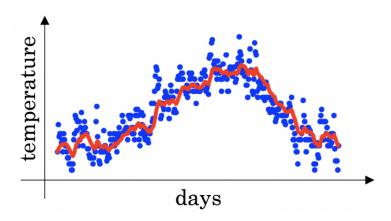

6. Which of these is NOT a good learning rate decay scheme? Here, t is the epoch number.

- $\bigcirc \quad \alpha = 0.95^t \alpha_0$
- $\alpha = \frac{1}{\sqrt{t}}\alpha_0$
- $\alpha = e^t \alpha_0$

You use an exponentially weighted average on the London temperature dataset. You use the following to track the temperature: $v_t = eta v_{t-1} + (1-eta) heta_t$. The red line below was computed using $\beta=0.9$. What would happen to your red curve as you vary β ? (Check the two that apply)

Decreasing β will shift the red line slightly to the right.

Un-selected is correct

Increasing β will shift the red line slightly to the right.

Correct

True, remember that the red line corresponds to $\beta=0.9$. In lecture we had a green line \$\beta = 0.98) that is slightly shifted to the right.

Decreasing β will create more oscillation within the red line.

True, remember that the red line corresponds to eta=0.9. In lecture we had a yellow line \$\$\beta = 0.98 that had a lot of oscillations.

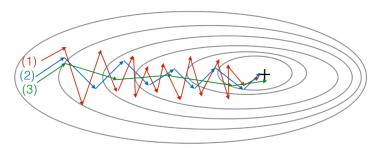

Increasing β will create more oscillations within the red line.

Un-selected is correct

Consider this figure:

These plots were generated with gradient descent; with gradient descent with momentum ($\!\beta$ = 0.5) and gradient descent with momentum (β = 0.9). Which curve corresponds to which algorithm?

(1) is gradient descent. (2) is gradient descent with momentum (large β). (3) is gradient descent with momentum (small β)

	(1) is gradient descent with momentum (small β). (2) is gradient descent. (3) is gradient descent with momentum (large β)		
		(1) is gradient descent with momentum (small β), (2) is gradient descent with momentum (small β), (3) is gradient descent	
		(1) is gradient descent. (2) is gradient descent with momentum (small β). (3) is gradient descent with momentum (large β)	
		Correct	
1/1 point	9.	Suppose batch gradient descent in a deep network is taking excessively long to find a value of the parameters that achieves a small value for the cost function $\mathcal{J}(W^{[1]}, b^{[1]},, W^{[L]}, b^{[L]})$. Which of the following techniques could help find parameter values that attain a small value for \mathcal{J} ? (Check all that apply)	
		Try initializing all the weights to zero	
		Un-selected is correct	
		Try mini-batch gradient descent	
		Correct	
		lacksquare Try tuning the learning rate $lpha$	
		Correct	
		Try better random initialization for the weights	
		Correct	
		Try using Adam	
		Correct	
•	10.	Which of the following statements about Adam is False?	
1/1		$ \qquad \qquad \text{The learning rate hyperparameter } \alpha \text{ in Adam usually needs to be tuned}. $	
point		We usually use "default" values for the hyperparameters eta_1,eta_2 and $arepsilon$ in Adam ($eta_1=0.9,eta_2=0.999,arepsilon=10^{-8}$)	
		Adam should be used with batch gradient computations, not with mini-batches.	
	Correct		
		Adam combines the advantages of RMSProp and momentum
